# Exercise 13: Parameters, Unpacking, Variables

In this exercise we will cover one more input method you can use to pass variables to a script (script being another name for your .py files). You know how you type  $python\ ex13.py$  to run the ex13.py file? Well the ex13.py part of the command is called an "argument." What we'll do now is write a script that also accepts arguments.

Type this program and I'll explain it in detail:

```
from sys import argv

script, first, second, third = argv

print "The script is called:", script
print "Your first variable is:", first
print "Your second variable is:", second
print "Your third variable is:", third
```

On line 1 we have what's called an "import." This is how you add features to your script from the Python feature set. Rather than give you all the features at once, Python asks you to say what you plan to use. This keeps your programs small, but it also acts as documentation for other programmers who read your code later.

The argv is the "argument variable," a very standard name in programming, that you will find used in many other languages. This variable *holds* the arguments you pass to your Python script when you run it. In the exercises you will get to play with this more and see what happens.

Line 3 "unpacks" argv so that, rather than holding all the arguments, it gets assigned to four variables you can work with: script, first, second, and third. This may look strange, but "unpack" is probably the best word to describe what it does. It just says, "Take whatever is in argv, unpack it, and assign it to all of these variables on the left in order."

After that we just print them out like normal.

# Hold Up! Features Have Another Name

I call them "features" here (these little things you import to make your Python program do more) but nobody else calls them features. I just used that name because I needed to trick you into learning what they are without jargon. Before you can continue, you need to learn their real name:

From now on we will be calling these "features" that we import modules. I'll say things like, "You want to import the sys module." They are also called "libraries" by other programmers, but let's just stick with modules.

### What You Should See

Run the program like this (and you *must* pass *three* command line arguments):

```
$ python ex13.py first 2nd 3rd
The script is called: ex13.py
Your first variable is: first
Your second variable is: 2nd
Your third variable is: 3rd
```

This is what you should see when you do a few different runs with different arguments:

```
$ python ex13.py stuff things that
```

```
The script is called: ex13.py
Your first variable is: stuff
Your second variable is: things
Your third variable is: that
$
$ python ex13.py apple orange grapefruit
The script is called: ex13.py
Your first variable is: apple
Your second variable is: orange
Your third variable is: grapefruit
You can actually replace first, 2nd, and 3rd with any three things you want.
```

If you do not run it correctly, then you will get an error like this:

```
$ python ex13.py first 2nd
Traceback (most recent call last):
    File "ex13.py", line 3, in <module>
        script, first, second, third = argv
ValueError: need more than 3 values to unpack
This happens when you do not put enough arguments on the command
when you run it (in this case just first 2nd). Notice when I run it I give it
first 2nd, which caused it to give an error about "need more than 3
values to unpack" telling you that you didn't give it enough parameters.
```

## **Study Drills**

- 1. Try giving fewer than three arguments to your script. See that error you get? See if you can explain it.
- 2. Write a script that has fewer arguments and one that has more. Make sure you give the unpacked variables good names.
- 3. Combine raw\_input with argv to make a script that gets more input from a user.
- 4. Remember that modules give you features. Modules. Modules. Remember this because we'll need it later.

### **Common Student Questions**

#### When I run it | get ValueError: need more than 1 value to unpack.

Remember that an important skill is paying attention to details. If you look at the *What You Should See* section you see that I run the script with parameters on the command line. You should replicate how I ran it exactly.

#### What's the difference between argv and raw\_input()?

The different has to do with where the user is required to give input. If they give your script inputs on the command line, then you use argv. If you want them to input using the keyboard while the script is running, then use raw\_input().

#### Are the command line arguments strings?

Yes, they come in as strings, even if you typed numbers on the command line. Use int() to convert them just like with raw\_input().

#### How do you use the command line?

You should have learned to use it real quick by now, but if you need to learn it at this stage, then read the Command Line Crash Course I wrote for this book in Appendix A.

#### I can't combine argv with raw input().

Don't overthink it. Just slap two lines at the end of this script that uses <code>raw\_input()</code> to get something and then print it. From that start playing with more ways to use both in the same script.

#### Why can't I do this raw input('?') = x?

Because that's backward to how it should work. Do it the way I do it and it'll work.

#### **Purchase The Videos For \$29.59**

For just \$29.59 you can get access to all the videos for Learn Python The Hard Way, **plus** a PDF of the book and no more popups all in

this one location. For \$29.59 you get:

- All 52 videos, 1 per exercise, almost 2G of video.
- A PDF of the book.
- Email help from the author.
- See a list of everything you get before you buy.

When you buy the videos they will immediately show up **right here** without any hassles.

#### Already Paid? Reactivate Your Purchase Right Now!

#### **Buying Is Easy**

Buying is easy. Just fill out the form below and we'll get started.
